

Method of hydro-break of bed includes sequential implementation of mini-hydro-break and powerful hydro-break of the bed. The mini-hydro-break is performed through pumping in to the bed micellar solution on the base of the oil sulphonates, this is left in the pump-compressor pipes and the drive pipe after implementation of the mini-hydro-break of the bed. The powerful hydro-break of the bed is started from pumping in technological fluid for break to the bed, without the crack fixative, to make wider and to develop the cracks, after this one pumps in technological fluid for break with the crack fixative. This method makes it possible to restrict filtration of technological fluid to the bed round the stem of the well and through the walls of the cracks, it promotes flow of technological fluid from the bed and the cracks at development of the well after hydro-break, this enlarges the oil inflow.
